where E_n is the energy of the electron in the n th energy level, and 13.6 eV is the energy of the electron in the ground state ($n = 1$). For example, when an electron in hydrogen transitions from the $n = 3$ level to the $n = 2$ level, the energy difference is: $E = E_3 - E_2 = - (13.6 \text{ eV} / 3^2) + (13.6 \text{ eV} / 2^2)$

It is shown that low SRO promotes rapid electron/ion mobility in the material, which enables HE energy storage materials to achieve higher capacity and multiplicity performance [86]. Compared to low-entropy materials, HEMs have a higher tolerance for lattice distortion, leading to a significant change in the energy distribution of ion diffusion.
