away dissolved gases. Steam flow may be parallel, cross, or counter to the water flow. The deaerator consists of a deaeration section, a storage tank, and a vent. In the deaeration section, steam bubbles through the water, both heating and agitating it. Steam is cooled by incoming water and condensed at the vent condenser.

At their core, steam storage tanks serve as reservoirs that hold pressurized steam under controlled conditions, offering a strategic buffer in steam distribution systems. This ...
