The dielectric constant and energy storage density of pure organic materials are relatively low. For example, the ϵ_r of polypropylene (PP) is 2.2 and the energy storage density is 1.2 J/cm^3 , while 12 and 2.4 J/cm^3 for polyvinylidene fluoride (PVDF).

First, the ultra-high dielectric constant of ceramic dielectrics and the improvement of the preparation process in recent years have led to their high breakdown strength, resulting in a very high energy storage density ($40\text{--}90 \text{ J cm}^{-3}$). The energy storage density of polymer-based multilayer dielectrics, on the other hand, is around 20 J cm^{-3} .

How to evaluate energy storage performance of dielectrics?

Besides U , U_{rec} , and i , the temperature stability, fatigue endurance, and discharge time are also important parameters for evaluating the energy storage performance of the dielectrics.

What makes a good energy storage dielectric?

An ideal energy storage dielectric should fit the requirements of high dielectric constant, large electric polarization, low-dielectric loss, low conductivity, large breakdown strength, and high fatigue cycles, and thermal stability, etc. However, it is very challenging for a single dielectric to meet these demanding requirements.
