What is a capacitor & how does it work?

A capacitor is a device designed to store electrical energy. The process of charging a capacitor entails transferring electric charges from one plate to another. The work done during this charging process is stored as electrical potential energy within the capacitor.

What happens if an uncharged capacitor is associated with a battery?

When an uncharged capacitor is associated with a battery then 50% of energy delivered by the battery is stored in the capacitor and the remaining 50% will be lost. Energy loss does not depend on the resistance of the circuit. Note: When initially capacitor is charged then heat loss is not equal to $21C V^2$, find heat loss by use of following concept
