How does a Magnetic Inductor work?

The voltage across the inductor pretty much depletes to zero exponentially, but there is still a current, therefore a magnetic field, therefore magnetic energy! The magnetic energy in an inductor is equal to the potential energy lost by the electrons that went through it before the resistance went to zero.

How does an inductor store energy?

An inductor stores energy in its magnetic field. As the current through the inductor increases, it forces the magnetic lines of force to expand against their natural tendency to shorten. This expansion stores energy in the magnetic field, similar to how a rubber band stores energy when stretched.

What is magnetic energy in an inductor?

The magnetic energy in an inductor is equal to the potential energy lost by the electrons that went through it before the resistance went to zero. The energy in an inductor is stored in the magnetic field which is generated by the current passing through the inductor.

How is the energy stored in an inductor calculated?

The energy stored in the magnetic field of an inductor can be written $asE = 0.5 *L *I^2$, where L is the inductance and I is the current flowing through the inductor.

When does the energy stored by an inductor stop increasing?

The energy stored by the inductor increases only while the current is building up to its steady-state value. When the current in a practical inductor reaches its steady-state value of Im = E/R, the magnetic field ceases to expand.

Why is the inductor releasing energy?

In this condition, the inductor is said to be releasing energy from its magnetic field to the rest of the circuit, as its store of energy is decreasing. This is known as discharging. Note the polarity of the voltage with regard to the direction of current.
