Can electrical energy storage solve the supply-demand balance problem?

As fossil fuel generation is progressively replaced with intermittent and less predictable renewable energy generation to decarbonize the power system, Electrical energy storage (EES) technologies are increasingly required to address the supply-demand balance challenge over a wide range of timescales.

Why do we need power transmission systems?

Power transmission systems are called upon to play a crucial role in the future decarbonized, electrified and digital energy sectors, as they constitute the most effective way of distributing vast amounts of electricity from renewable energy sources to faraway locations.

Does storage reduce the need for transmission capacity and dispatchable renewables?

We observe that storage decreases the need for transmission capacity and dispatchable renewables like biomass while shifting the solar and wind balance (Fig. 5b). Due to the significant drop in curtailment for scenarios up to 20 TWh, less generation capacity is needed to deliver the same energy to the grid.

How much storage does a solar-dominant load zone use?

A closer look at the distribution of storage resources in a solar-dominant and wind-dominant scenario (Fig. 3) confirms that nearly all solar-dominant load zones use 6-to-10-h storage, while nearly all wind-dominant load zones use 10-to-20-h storage.

How important are storage power capacity mandates?

Overall, in the past storage power capacity mandates have had an important impact; for example, the California Public Utilities Commission required the procurement of 1.3 GW of energy storage by 2020 ⁵¹ and several states have followed this initiative ³⁹.

Will pumped storage increase global hydropower capacity?

If one-tenth of the global conventional hydropower capacity ⁵ is technically eligible for similar-scale pumped storage renovations, this could result in an increase of over 120 GW in storage capacity-- 1.2 times greater than the total capacity of all other energy storage technologies worldwide.

The energy platform also requires breakthroughs in large scale energy storage and many other areas including efficient power electronics, sensors and controls, new mathematical and computational tools, and deep integration of energy technologies and information sciences to control and stabilize such complex chaotic systems.

"Urgent action must be taken to avoid lagging grid infrastructures, which would delay the energy transition," wrote Adrian Gonzelez, programme officer, innovation and end-use sectors at IRENA.

The Office of Electricity's (OE) Energy Storage Division accelerates bi-directional electrical energy storage technologies as a key component of the future-ready grid. The Division supports applied materials development to identify safe, low-cost, and earth-abundant elements that enable cost-effective long-duration storage.

The paper is organized as follows: Section 2 provides a brief historical perspective of both AC and DC transmission technologies. It is illustrated how, for decades, the AC/DC transmission devices evolved to overcome the diverse static and dynamic constraints derived from the need to safely and efficiently transmit greater amounts of energy at greater distances.

Storage can provide similar start-up power to larger power plants, if the storage system is suitably sited and there is a clear transmission path to the power plant from the storage system's location. Storage system size range: 5-50 MW Target discharge duration range: 15 minutes to 1 hour Minimum cycles/year: 10-20.
