

What is switch power system planning?

Switch is an open-source power system planning model that is uniquely suited for designing and studying future power systems that may have large shares of renewable energy, storage and/or demand response.

Does storage reduce the need for transmission capacity and dispatchable renewables?

We observe that storage decreases the need for transmission capacity and dispatchable renewables like biomass while shifting the solar and wind balance (Fig. 5b). Due to the significant drop in curtailment for scenarios up to 20 TWh, less generation capacity is needed to deliver the same energy to the grid.

How long does a grid need to store electricity?

First, our results suggest to industry and grid planners that the cost-effective duration for storage is closely tied to the grid's generation mix. Solar-dominant grids tend to need 6-to-8-h storage while wind-dominant grids have a greater need for 10-to-20-h storage.

Can energy storage reduce the need for transmission expansion?

The ability of energy storage to reduce the need for transmission expansion is significant since transmission expansion is often challenging from a political and regulatory perspective.

How does switch work?

Switch uses a state-of-the mathematical formulation that considers multiple investment periods and chronologically sequences of hours, enabling optimization and assessment of a long-term renewable transition based on a direct consideration of how these resources would be used hour-by-hour.

How does energy storage affect energy prices?

As energy storage is added to the grid, the high July and December prices are reduced but prices in neighbouring months increase. In the 20 TWh scenario, average marginal prices for July, August, November, December and January range from 52 to 100 \$/MWh while other months average 35 \$/MWh or less.
